Integration Issues and Migration Benefits

Technical client report | Original Base44 application and proposed Supabase + Vercel setup

Client issue	Finding in the original Base44 code
1. Missing transcripts	**recallCalendarWebhook: bot.done** inserts a CallLog before transcription is necessarily complete. On **transcript.done**, an empty transcript returns HTTP 200 with 'transcript still empty', so that delivery is treated as handled. **syncRecallCalls** fetches only 50 completed bots, does not follow the next page, and identifies existing calls by title and date rather than bot ID.
2. Calendar connection	**recallCalendarWebhook** compares the event name to **calendar.updated**; Recall sends **calendar.update**. The disconnect/status branch therefore does not run for the documented event. **recallCalendarOAuth** always creates a new Recall calendar and local record after authorization; it does not update an existing connection.
3. Monday.com updates	**mondayOAuth** requests **boards:read** in its authorization path, while **processCallRiskToMonday** calls **create_update** and **change_simple_column_value**. The status mutation's HTTP/GraphQL result is not checked before returning **monday_updated: true**. Item matching scans only 20 boards and 100 items per board by company name; missing client IDs or connections cause early skips.
4. Bot missing meetings	On **calendar.sync_events**, the handler processes only **eventsData.results** and never follows the pagination URL. It skips an event when **start_time <= now**. A failed scheduling POST is added to 'skipped', but the webhook still returns HTTP 200 with no retry. On success, **botData.id** is recorded as the bot ID although the response's bot ID is under **bots[].bot_id**; that last defect affects tracking.

Benefits of moving to the local project, then Vercel

Data isolation: A separate Supabase database and per-user access rules isolate development records from the live Base44 database.
Recoverable processing: The local backend includes webhook receipts, persisted bot/event states, paginated event fetching, and a reconciliation function for missed calendar events and transcripts.
Clear hosting roles: Vercel serves the frontend; Supabase runs authentication, database, webhooks, and server functions. The local call analysis uses explicit rules rather than Base44 AI.

Verification boundary: These are source-code failure paths, not proof of the cause of any specific historical incident. The new deployment must be configured and checked with real OAuth connections, webhooks, completed calls, and Monday updates before it can be presented as fully resolved.
